ABSTRACT

Eddy current (EC) method is widely applied for manual inspection of semi-finished components for the purpose of the surface defect detection. The manual inspection of large forgings by EC method is time consuming due small size of probe needed for sensitive crack detection. To solve this problem special EDDYLINE type EC One-Channel Array probe was developed. EDDYLINE type EC probe consists of 5 separate EC probes connected by specially developed matching unit to summarize the signal responses of each separate EC probe for operation with one channel flaw detector. All separate EC probes are realized by double differential scheme for better noise suppression. Due such connection high sensitivity length (near 60 mm) was created. At the same time high locality was provided because each of EC probes is operated separately with the same sensitivity as before connection. Developed EC probes in combination with ELOTEST B300 flaw detector were successfully applied for detection of cracks in ferromagnetic and stainless steel tube forgings.

Keywords: Tube forging, Eddy Current Probe, Carbon Steel, Stainless Steel

1. Introduction

Forgings are formed from ingots or billets, which are shaped by hammers or presses by forcing the solid metal into a die cavity. One of the main type of defects associated with forgings are the surface defects which can arise during the working of the ingot (or billet) [1]. Eddy current (EC) method is widely applied for inspection of semi-finished components (like forgings) for the purpose of the surface defect detection. The manual inspection of large forgings by EC method is time consuming due small size of probe needed for sensitive crack detection. In this case the EC probes with elongated sensitivity area are applied to increase the inspection productivity. But such probes don’t secure the sensitivity requirements assurance due low performance characteristic. Best productivity can be achieved by application of the multiplexing inspection systems based on array type probes. But such systems are expensive enough and difficult in recalibration for different size forgings.
2. **New eddy current probe for manual inspection of forgings**

For inspection productivity enhancement special EDDYLINE type EC One-Channel Array probe was developed. EDDYLINE type EC probe consists of 5 separate EC probes connected by specially developed matching unit to summarize the signal responses of each separate EC probe for operation with one channel flaw detector. All separate EC probes are realized by double differential scheme for better noise suppression [2]. Each of these probes is installed inside the 12 mm diameter cylindrical aluminum case. Due such connection high sensitivity length (near 60 mm) was created. At the same time high locality was provided because each of EC probes is operated separately with the same sensitivity as before connection. Developed EC probes in combination with ELOTEST B300 flaw detector were successfully applied for detection of cracks in ferromagnetic and stainless steel tube forgings.

**Fig. 1**: Principle of inspection by one-channel EDDYLINE type EC probe application:
1 – EDDYLINE type EC probe; 2-6 – double differential type EC probes; 7 – matching unit; 8 – connecting cable; 9 – flaw detector; 10 – inspected specimen; 11 – flaw.

3. **Investigation and calibration of EDDYLINE type EC probe**

The investigations were carried out with application of the special reference standard specimen fabricated from ferrous steel 45 with smooth (A – Ra 1.25 μm) and rough (B – Rz 160 μm) surfaces (fig. 2). Surface roughness on the surface B is simulated in the form of the sawcut grid with sawcut pitch, thickness and depth 1.0; 0.5 and 0.16 mm respectively. The artificial electrical-discharge-machined slots were 0.1 mm wide 30 mm long with depth 0.1; 0.2; 0.5; 1.0 and 2.0 mm on the smooth surface A and 0.6; 1.5 and 3.0 mm on the rough surface B.

**Fig. 2**: Specimen for EDDYLINE type EC probe investigations.
All defects on both (A and B) surfaces in presented specimen were successfully detected with high signal to noise ratio.

Let us consider the specificity of EDDYLINE type EC probe. Fig. 3a show the signals of EDDYLINE type EC probe from shallowest 0.1 and 0.2 mm depth slots in situation when only one separate EC probe was scanned across the flaw area. At this time other 4 probes were situated out of specimen (in the air). Next picture (Fig. 3b) show the signals of the same slots when two double differential type EC probes were scanned across the flaw area simultaneously. And last picture (Fig. 3c) show the signals of the same slots when three double differential type EC probes were scanned across the flaw area at the same time.

Fig. 3: EDDYLINE type EC probe signals in complex plane ($a_1^1, b_1^1, c_1^1$) and in time base mode ($a_2^1, b_2^1, c_2^1$) for one (a), two (b) and three (c) probes scanning across the shallowest 0.1 and 0.2 mm depth slots.

Thus each of additional probes scanned across the long crack increase the signal amplitude proportionally to the number of probes transferred across the flaw. Fig. 4 shows the lift-off signal of EDDYLINE type EC probe in complex plane and in time-base mode for comparison. You can see the opposite direction of lift-off signal (Fig. 4) in comparison with signals from the flaws (Fig. 3).
Fig. 4: Lift-off signals of EDDYLINE type probe in complex plane (a) and in time-base mode (b).

Special specimens with 0.2; 0.3; 0.5; 1.0 and 2.0 mm depths electrodischarge slots were produced for calibration of the EDDYLINE type EC probe before inspection (Fig. 5)

Fig. 5: Ferromagnetic (a) and stainless (b) steel specimens with EDDYLINE type EC probe.

Fig. 6 show the signals of EDDYLINE type EC probe from 0.2 and 0.5 mm depth slots in ferromagnetic steel specimen on the screen of ELOTEST B 300 flaw detector on operational frequency 200 kHz.

Fig. 6: Signals in complex plane obtained for 0.2 mm (a) and 0.5 mm (b) depths electrodischarge slots in ferromagnetic steel specimen (upward) and lift-off signal (downward).
Fig. 7 show the signals of EDDYLINE type EC probe from 0.2 and 0.5 mm depth slots in stainless steel (nonferromagnetic) specimen on the screen of ELOTEST B 300 flaw detector on operational frequency 610 kHz.

![Signals in complex plane obtained for 0.2 mm (a) and 0.5 mm (b) depths electrodischarge slots in stainless steel specimen (upward) and lift-off signal (downward).](image)

Fig. 7: Signals in complex plane obtained for 0.2 mm (a) and 0.5 mm (b) depths electrodischarge slots in stainless steel specimen (upward) and lift-off signal (downward).

Fig. 6 and Fig. 7 show the differentiation of flaw signals and lift-off by the hodograph direction. Such feature permits to improve the inspection reliability. Application of EDDYLINE type EC probes facilitates the increase in inspection productivity 4…5 times.

4. Conclusions

4.1 New EDDYLINE type EC one-channel array probe was developed to increase the inspection productivity.
4.2. Application of EDDYLINE type EC probes facilitates the increase in inspection productivity and reliability.
4.3. EDDYLINE type EC probes in connection with one-channel ELOTEST B300 type flaw detector were successfully applied for inspection of different kind of forgings.
